

# Hyperspectral Image Analysis for Visualizing Grain Compounds

Morten Arngren

FOSS Analytical A/S & DTU Informatic

TCD, Sep. 2009

# Outline

## ① Introduction

- ▶ What are these hyperspectral images?
- ▶ The linear and convex geometry model.
- ▶ Wheat and maize kernel data.

## ② Image Acquisition & Processing

- ▶ The hyperspectral camera.
- ▶ Pre-processing pipeline.

## ③ The Unmixing Model

- ▶ Decomposing wheat and maize kernels.

## ④ Conclusion and summary.

# Hyperspectral image analysis

## Introduction

- ▶ Classic image analysis is usually conducted on photographs having up to 3 RGB colors, sufficient for visualization.
- ▶ *Hyperspectral images* includes multiple color bands, typically  $> 50$  bands and thus offers a more detailed analysis.

Figure 1 : Example of hyperspectral image. Each pixel consist of a 150 band spectra.

- ▶ Light reflection from sample contains information of material.
- ▶ The observed spectra is dominated by a **linear mix** of pure components.
- ▶ The objective is to decompose the image to into these pure spectral signatures.

## Linear Modeling

The mixing of the constituents can be approximated linearly as

$$\mathbf{X} = \mathbf{WH} + \epsilon, \quad (1)$$

where  $\mathbf{W}$  are the spectral signatures,  $\mathbf{H}$  denote the fractional abundances (concentrations) and  $\epsilon$  is the residual white Gaussian noise.

Constraints

- ▶ **Non-Negativity**, intensities can not be negative :

$$x_{i,j} \geq 0 \quad \wedge \quad w_{i,j} \geq 0 \quad \wedge \quad h_{i,j} \geq 0 \quad (2)$$

- ▶ **Additivity**, concentrations must sum to one :  $\sum_i h_{i,j} = 1$

Figure 2 : Linear mixing of spectral signature into observed pixel spectra.

## Convex Geometry Model

- ▶ These constraints lead to the following geometry for the 2 component case.

Figure 3 : Simple mixing with only 2 vertices.

- ▶ **Purple** vertices are the basis vertices denoted *endmembers*.
- ▶ **Red** points inside designate valid observed samples.
- ▶ **Gray** points outside are invalid due to noise (constraints violated).

For multiple endmembers the structure becomes an N-simplex.

Figure 4 : 3- and 4-simplex (image from Wikipedia).

**Objective** is to locate the vertices as the basis spectral signatures based only on the observed data (unsupervised learning).

## Grain Kernel Datasets

Expected identifiable components in grain kernels:

- ▶ **Starch** in endosperm (maize has both horny and flouly starch).
- ▶ **Protein** in a matrix structure with starch and in aleurone layer.
- ▶ **Oil** in the germ.
- ▶ **Background** pixels.

Figure 5 : Wheat kernel anatomy.

Figure 6 : Maize kernel anatomy with both horny and flouly starch.

## Image Acquisition

- ▶ Hyperspectral line-scan NIR camera sensitive from 900 – 1700nm in 165 bands.
- ▶ Two datasets: **14 Wheat kernels** and **8 Maize kernels** (front and backside).
- ▶ Data format of each image is a  $320 \times 150 \times 165$  tensor.
- ▶ Unfortunately no ground truth reference set, e.g. single kernel protein levels.

Figure 7 : Hyperspectral camera setup.

Figure 8 : Grain kernel datasets.

# Data Processing Pipeline

Prior to decomposing the hyperspectral data a series of pre-processing steps are taken.

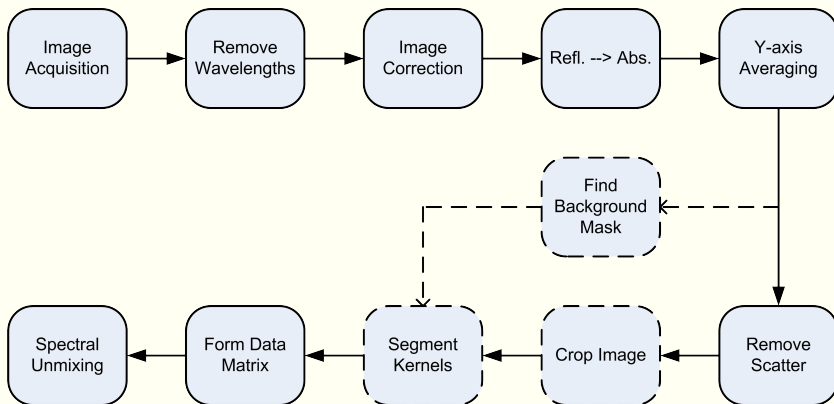

Figure 9 : Pre-processing pipeline.

## Initial Pre-Processing

- ▶ Remove spectral range: Poor response at 900-950nm & 1650-1700nm (165 → 145 bands).
- ▶ Image correction: White reference and dark current image compensation.
- ▶ Line y-axis averaging:  $2 \times$  Oversampling.
- ▶ Convert to Absorbance.

Figure 10 : White reference and dark current spectra.

- ▶ White light source to show poor SNR at spectral edges.
- ▶ Spectral dip at 1430nm is due to light guide fiber characteristics.

## Scatter effects

- ▶ Main contribution to scatter effect appear due to surface structures of grains.
- ▶ Different types of scatter removal approaches: [MSC](#), [SNV](#), [Detrending \(Cubic Splines, SG-Smoothing etc.\)](#), [Derivatives etc.](#)
- ▶ NIR spectra are very smooth and thus complex detrending can prove fatal as important spectral information is suppressed.

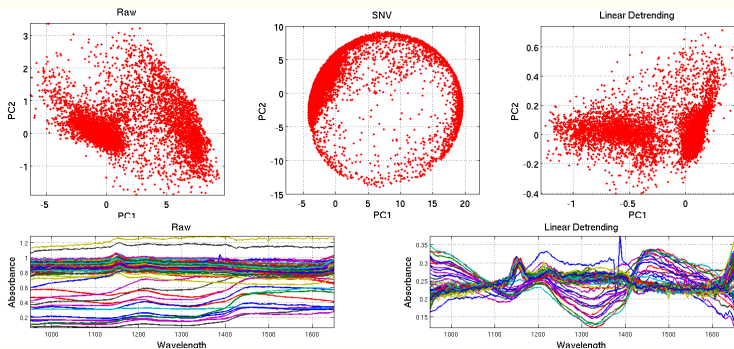

Figure 11 : Comparison of different anticscatter approaches.

## Wheat Kernel Segmentation

- ▶ Each kernel is cropped into small  $26 \times 44 \times 145$  images.
- ▶ Background pixels (black cardboard) are identified by a simple threshold applied to the 1st PC image.

Figure 12 : Principal component images.

Figure 13 : Segmented wheat kernel images.

## The Unmixing Model

- ▶ Linear NMF model  $\mathbf{X} = \mathbf{WH} + \epsilon$  subject to the constraints (2).
- ▶ Augmented **volume regularization** with cost function

$$E = \frac{1}{2} \|\mathbf{X} - \mathbf{WH}\|^2 + \lambda J_W(\mathbf{W}) \quad (3)$$

- ▶ Regularization term  $J_W(\mathbf{W})$  encourages tight volume of simplex around the observed data points.

Figure 14 : No regularization

Figure 15 : Optimal regularization.

- ▶ Model parameter  $\lambda$  can be tuned to suppress inherit noise.

## Wheat Kernel Dataset

- Constituents successfully identified: *Starch*, *Oil* and *Background*.

Figure 16 : Image components in wheat kernel dataset.

Figure 17 : Pure spectral signatures.

Figure 18 : Reference spectral signatures.

- Limitations: High correlation between constituents, mixing profile of compounds (simplex not filled) and penetration depth (difficult to assess).

## Maize Kernel Dataset

- Constituents successfully identified: *Starch (Horny & Floury)*, *Oil*, *Background* and *Shadows*.

Figure 19 : Image components in maize kernel dataset.

Figure 20 : Image component and spectral signatures.

## Advanced Models

### Bayesian NMF with volume prior

- Bayesian framework leads to probability distributions providing confidence of endmember estimate.

Figure 21 : Bayesian volume NMF applied on wheat kernel dataset.

- Achieve variance estimation not acquired by regular NMF.

# Summary

## Conclusions

- ▶ Hyperspectral images can be decomposed efficiently using NMF algorithms with *volume* regularizations.
- ▶ Pre-processing of data is important to achieve reasonable decomposition.
- ▶ Structure of dataset can set limitations, such as component correlation and mixing profile.

## Near future work

- ▶ Incorporate spatial information, e.g. smoothing.
